DECLARATION OF MELUR K. RAGHURAMAN AND VENKATARAMAN RAMANATHAN UNDER 37 C.F.R. § 1.131

Mail Stop Amendment
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

We, Melur K. Raghuraman and Venkataraman Ramanthan, hereby declare the following:

1. We are the original, joint inventors of the subject matter claimed and disclosed in the above-captioned application.

2. We have been informed that the above-captioned application, U.S. Application Serial No. 09/490,981 was filed January 24, 2000 ("the Application").

3. We submit this Declaration for the purpose of providing evidence that the subject matter claimed in the Application was conceived and reduced to practice in the United States of America as of a date prior in time to February 12, 1999.

4. We have also been informed that Spasojevic, U.S. Patent 6,269,410 (hereinafter, "Spasojevic;" a copy of which is attached hereto as Exhibit "A") was cited against the claims pending in the Application.

5. We have been informed that the effective date of Spasojevic as an alleged prior art reference is February 12, 1999.

6. We have read and understood Spasojevic, attached as Exhibit A.

7. To establish the conception date of our invention prior to February 12, 1999, we provide evidence in the form of an article we authored entitled "Network Performance Monitoring in Windows NT" (hereinafter, "the article;" a copy of which is attached hereto as Exhibit "B") which describes facts relating to each and every element of claims 4-6, 10, 15, 17, and 18 as required by M.P.E.P. 715.07 to satisfy 37 C.F.R. § 1.131. The article describes the invention of the above-noted patent application, and specifically includes a description of a method for tracing both transmission and receipt of data within a computer network to facilitate network monitoring. In particular, the article describes a method of tracing a transmission of data over a computer network comprising: detecting a transport-layer request to transmit an input/output packet; searching the input/output packet to determine an identity of a process that created the input/output packet; and storing in a trace log an entry representing the request, wherein the entry comprises the identity of the process, and wherein the trace log is accessible to determine a volume of data being transmitted over the network.

8. To establish a date of actual reduction to practice of our invention prior to February 12, 1999, we provide a sample of our invention's output in the form of a kernel trace fragment from a TCP Send test, translated into readable text format, as presented in Appendix A

of our article and originally obtained using the Method of Tracing Data Traffic on a Network. The article describes this output in relation to the tracing method presented by both the article and the present application. Particularly, the article's "Analysis of sample Traces" section associates all essential elements of our present application to the sample output. First, the article describes detecting a transport-layer request to transmit an input/output packet as the appearance of TCP Send events. Second, the output analysis explains searching the input/output packet to determine the identity of a process that created the input/output packet by presenting both the source IP address/port and destination IP address/port. Finally, the article illustrates storing in a trace log an entry representing the request, wherein the entry comprises the identity of the process by explaining that the "the process ID...[is] saved when the connection was created [and] is... recorded with every send event." By completing these three steps, which resulted in the output presented and described by the article, we concluded, prior to February 12, 1999, that the network traffic can be properly charged to processes from the trace, thereby satisfying the object of the present application as evidence of actual reduction to practice.

9. To further establish evidence of actual reduction to practice prior to February 12, 1999, the article describes additional elements of our present application in the "Event Tracing Sends / Receives" section. This section of the article describes all elements of our invention including detecting an acknowledgement of the transmission and storing in the trace log an entry representing the completion of the transmission. Particularly, this portion of the article proposes tracing a receipt of data from a computer network comprising: detecting a transport-layer request to transmit a packet for an input/output connection to a port; searching the packet to determine an identity of a process that created the packet; and in response to the detection of a receipt of data at the port, storing in a trace log an entry representing the receipt of the data, wherein the entry

comprises the process identification, and wherein the trace log is accessible to determine a volume of the data being transmitted over the network.

10. Similarly, the "Event Tracing Sends / Receives" section along with other portions of the article describe a facility for tracing data traffic on a network at the transport layer, the facility comprising: an identifying means for identifying a process causing a transport-layer request to transmit data via the network; and a logging means in communication with the identifying means for logging an event, wherein the event comprises the identification of the process and wherein the logging means is useable to determine a volume of data traveling over the network.

11. The article further describes a computer-readable medium having stored thereon computer-executable instructions for performing steps comprising: detecting a transport-layer request to transmit an input/output packet; searching the input/output packet to determine an identity of a process that created the input/output packet; and storing in a trace log an entry representing the request, wherein the entry comprises the identity of the process, and wherein the trace log is accessible to determine a volume of data being transmitted over the network. The article also teaches the additional step of detecting an acknowledgment, storing in the trace log an entry representing the completion of the transmission.

12. Finally, the article explains a computer-readable medium having stored thereon computer-executable instructions for performing the steps comprising: detecting a transport-layer request to transmit a packet for an input-output connection to a port; searching the packet to determine an identity of a process that created the packet; and in response to the detection of a receipt of data at the port, storing in a trace log an entry representing the receipt of the data,

wherein the entry comprises process identification, and wherein the trace log is accessible to determine the volume of the data being transmitted over the network.

13. We wrote the article in the United States of America, where our invention was also conceived, prior to February 12, 1999. We support this assertion with the attached Exhibit "C" showing that we presented the findings of this article on December 8, 1998 in Anaheim, California, U.S.A., as part of the International Computer Measurement Group Conference.

14. All statements made herein of our own knowledge are true and all statements made on information and belief are believed to be true; and further these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and such willful false statements may jeopardize the validity of the application or patent issued thereon.

Network Performance Monitoring in Windows NT

Melur Raghuraman & Venkat Ramanathan
Microsoft Corporation

Abstract

Most capacity planning efforts for networks have treated the system as a source generator and focused on frame counts and frame bytes by listening to the wire. Some have employed smart ways of identifying the application responsible for network traffic by scanning the packet headers. These methods are expensive and arbitrary. In this paper, we present trace instrumentation of the TCP/IP stack in Windows NT that provides key information for capacity planners for correctly charging network traffic to the individual services and applications.

Introduction

In this client/server world of computing that we live in today, capacity planning activity is just not limited to the server but to the entire system including the clients, servers and network devices. In the past, network capacity planners have treated the systems without serious concern and system capacity planners have in turn ignored the network devices in their analysis. One major reason for this is the lack of appropriate performance data to tie the two worlds and the fear of overhead of instrumentation.

Accuracy of model input metrics is often cited as the key indicator of the validity of a capacity analysis. In the last couple of years, there have been several papers in this conference mentioning the lack of performance data in Microsoft® Windows NT® operating system mainly for Capacity Planning [1,2]. We addressed these concerns by introducing an Event Tracing Facility in Windows NT 5.0 and published the event tracing API[3] in this conference last year. While it addressed system data requirements adequately, data related to network was lacking. The purpose of this paper is to describe the network instrumentation work that has been done to complement the kernel trace instrumentation work for Windows NT 5.0.

With internet access becoming common place today, there is no drop in the appetite for network bandwidth for web based applications. In fact, high speed networking is a very important focus of Windows NT 5.0 which already achieves 1 to 2 Gbps throughput. With network speeds getting this fast, any instrumentation must be highly optimized to take minimal overhead.

In order to place the network instrumentation in the larger context of Networking layers in Windows NT, we devote the next section to describe the networking architecture in Windows NT. We describe the capacity planning data requirements for Networks and what data is collected through the instrumentation. Sample trace data from our experiments are also presented.

Event Tracing in Windows NT 5.0

The next version of Microsoft Windows NT operating system will have a uniform framework for event tracing, specifically for capacity planning. The event tracing mechanism implements a circular buffer pool maintained by the operating system and an API set for Trace Providers, Consumers and Management Control. The trace logger can accept data from kernel mode device drivers and user mode applications. In addition to providing a facility to log trace data for applications, the Windows NT kernel has been instrumented to provide key capacity planning metrics that were not available through the commonly used performance tool 'Perfmon'. The following system events are instrumented:

1. *Process Creation/Deletion* event. The ProcessId, parent process Id, Security Id and the Image File name are recorded.
2. *Thread Creation/Deletion* event. The Thread Id and its process Id are also recorded.
3. *Hard Page fault* event. The disk signature and the size of the first disk read resulting from the page fault are also recorded.
4. *Disk Read/Write* event. The disk signature and the size of the operation are recorded.

Multiple logger streams may be active at one time, typically one for the kernel logger and one for each of the trace-enabled applications running on a server. The Consumer APIset makes it easy to process the trace from multiple logger streams in the proper order and returned to the caller one event at a time.

Networking Architecture in Windows NT

Networking capabilities are built into Windows NT and it is organized as layers (See Figure 1).

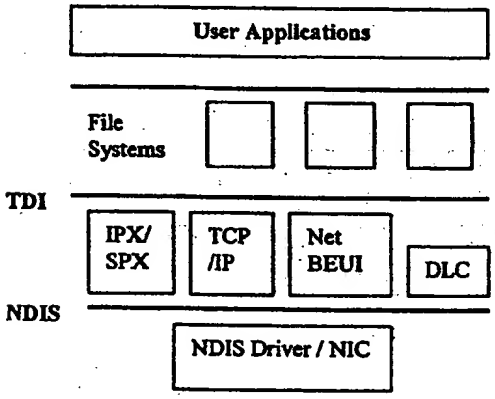

Figure 1. Windows NT Network Layers

Windows NT networking components include:

- Transport protocols (DLC, NetBEUI, NWLink, and TCP/IP) define the rules governing communications between two computers.
- Inter-process communication (IPC) components, such as named pipes and mail slots, allow applications to communicate with each other over a network.
- File and Print sharing components allow resources to be made available on a network.

The Multiple uniform naming convention (UNC) Provider (MUP) and Multi-Provider Router (MPR) make it possible to write applications that use a single API to communicate using any network vendor's redirector.

There are two boundary layers in the architecture, namely the Network Driver Interface Specification (NDIS) and Transport Driver Interface (TDI). The NDIS layer provides the interface and a wrapper to the Network Interface Card (NIC) device drivers. The TDI boundary layer provides a common interface specification to communicate with various transport drivers. While several protocols are supported in the transport layer, TCP/IP forms the main focal point for all networking activity.

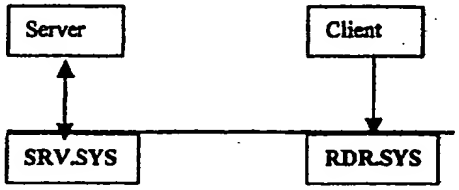
The protocol suite benefits from years of research and is the most favored suite in the Internet. In WindowsNT, several services make use of TCP/IP stack, most notably File/Print services and Socket-based applications. Most services require reliable data transmission and use TCP/IP suite for end to end reliable delivery. We will explain the File/Print services and Sockets in more detail in the next section.

File and Print Services

The File and Print services are supported by two services (Redirector and Server) that are layered on top of Transport Driver Interface layer as shown in Figure 2. They provide an encapsulation over the file system and network transparency for applications accessing remote files.

When a process on a Windows NT system tries to open a file that resides on a remote computer, the following steps occur:

- The process calls the I/O Manager to request that the file be opened.
- The I/O Manager recognizes that the request is for a file on a remote computer, so it passes it to the redirector file system driver (RDR.Sys).
- The redirector passes the request to lower-level network drivers that transmit it to the remote Server for processing.
- The transport receives a send IO request packet (Irp) for the SMB header and command.
- This send is translated into frames and queued for dispatch on the wire through the Miniport driver.



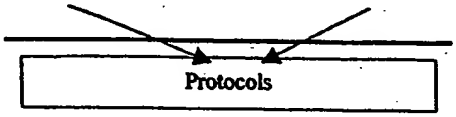


Figure 2. Server and Workstation Services

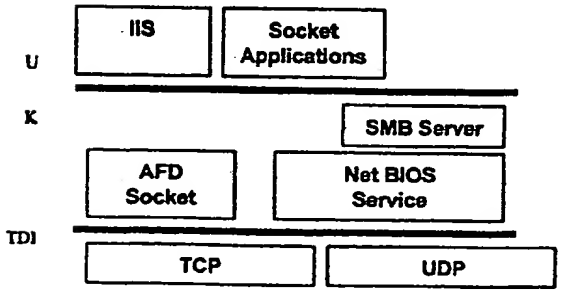
On the remote WindowsNT server system, when the server service receives a request from a remote computer asking it to read a file that resides on the hard disk, the following steps occur:

- The low-level network drivers receive the request and pass it to the server driver (SRV.SYS).
- The server passes a file read request to the appropriate local file system driver.
- The local file system driver calls lower-level disk device drivers to access the file.
- The data is passed back to the local file system driver.
- The local file system driver passes the data back to the server.
- The server passes the data to the lower-level network drivers for transmission back to the client computer.

Socket-based Applications

Socket-based applications are supported through the Windows Socket Provider (WinSock). Figure 3 shows the relationship between various modules and TCP/IP.

A Socket based user application that would like to provide a service on port P (pre-advertised) to all clients would open up a socket through WinSock and listen on the socket for connection requests. This would translate as an address object with TCB structures listening on that port with the server's IP address(es) and a wild-card IP address to denote client addresses.



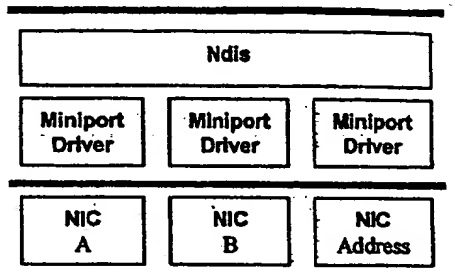


Figure 3. TCP/IP Stack

When a client requests a connection, a frame comes in on one of the NICs (with the client's IP address and connecting port #) and is tied to one of these TCB structures. TCP calls across TDI to indicate to the socket provider, which in turn calls into the User's service application for acceptance. Once accepted, frames are received and sent on the NIC involved in the connection. Though the physical NIC through which the connection data is routed can change over time, the IP addresses and port numbers don't change and lend themselves as connection context for event tracing.

The user application requests a Send to the socket service provider with a pointer to the data. The socket provider, namely AFD will lock the pages in memory and request TCP across TDI to send. TCP cuts the requests to frames and calls the miniport driver corresponding to the NIC through which the data needs to be transmitted. The Miniport driver sends the frames and calls to TCP to complete each frame-send event. The TCP requests are processed asynchronously as a rule, and could happen in the context of the system thread dispatched by the socket provider or a DPC (Deferred Procedure Call) from Ndis.

In the case of receive, the miniport driver services the interrupt and through Ndis, queues a DPC to process the frame. This DPC identifies the protocol stack and calls the appropriate Receive Event handler. When this thread executes TCP Receive routine in its context, the data is indicated up or is filled in pre-posted receive buffers from the application.

Event Tracing Sends / Receives

A TCP Send needs to be traced at the end of the send. The end of a send is marked by the processing of an ACK(acknowledgement) from the other connection endpoint corresponding to the last byte of the send. Through TDI, TCP receives an IoRequestPacket (IRP) from AFD with a pointer to a locked user buffer / locked set of pages from a file's cached view. TCP creates a Send-Request structure, which caches this IRP, splits the data into frames, and sends them across. When the last ack (ack acknowledging the last byte sent) arrives, part of receive processing involves queuing the corresponding Send-Request for completion. When the completion queue is processed, the cached IRP is completed to the upper layer.

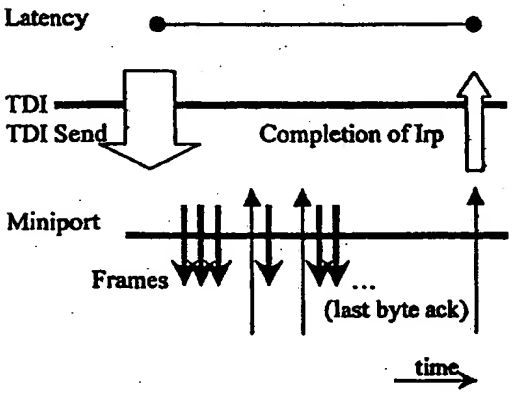

Figure 4. TCP Send

Between the initiation of the Send and the completion, several copies of the data could get transmitted due to retransmissions, or the send could get cancelled, in which case, a completion doesn't occur. In Fig 4., the timeline of events during a send is explained. Since only the completion is traced, the use of the NIC to send out the said number of bytes is guaranteed. Also, as far as the user application is concerned, the Send through Tdi completed only when the IRP is completed in the socket driver (which may wake up the blocked thread in the case of synchronous i/o or trigger the appropriate event in the case of async i/o).

Tracing receives is more complex than Sends, in the sense that tracing information needs to be generated at more points than one. In the case of receive, we should not care if the TCP protocol sends out acks or if this is only part of a receive which got cancelled from the other end point. The number of bytes received must be accounted for exactly. We will first take the case of a pre-posted receive and how it is traced for capacity planning purposes.

In the case of pre-posted receives, TCP receives an IRP through TDI to receive a certain size. TCP caches this IRP in a Receive-Request structure. When a chunk of a certain size of data is received (could be less than the requested size, to improve latency) TCP completes the request with the then-available number of bytes and the appropriate buffers. If more needs to be received, the receiver (say application through socket interface) posts more receive-IRPs which are completed as frames are received. In Fig 5., the receive completion and trace timing is explained.

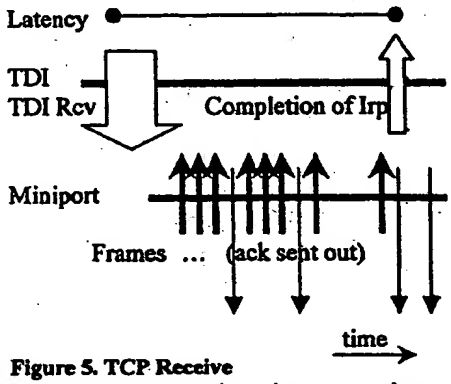

Figure 5. TCP Receive

It is possible to receive when no receives are posted. In such cases, the data is indicated to the receiver as soon as the first frame is received. If any more data needs to be received, TCP receives a piggybacked Irp. TCP generates a CP trace in this indicate path to accurately account for the accepted number of bytes.

Data Collection Issues

Windows NT uses a packet oriented I/O model for performing I/O operations to disks as well as to network devices. Whenever a user application or service posts a Send/Receive request, an IRP is created and sent to TCP. Typically the IRP is filled with the context of the thread requesting the operation. In the case of sends, it is possible to identify the correct user thread to charge the bandwidth utilization. In the case of receives, a DPC is generated in NDIS, which doesn't run in the context of any user thread. With respect to receives through the indicate-path described

above, when the data is accepted without requesting more receives through IRPs, it is not possible to make a correspondence. In such cases however, the port information that is provided is useful in identifying the service.

What is Instrumented?

1. *Send Complete* event when a TCP send request is complete (when an ACK for the last byte of the Send Request is received). The source address, destination address, source port number, destination port number, bytes transmitted are also recorded. Events are automatically time-stamped by the trace logger.
2. *Receive Indicate* event when incoming data is indicated to the upper layers. The source address, destination address, source port and destination port numbers, the size of data received and the process Id of the Process that is being indicated by TCP.
3. *Receive Complete* event (when a receive-Irp is completed with data). Similar information is collected.

These three trace points cover the majority of the meaningful TCP traffic in the system. It is important to keep in mind that some TCP traffic is not accounted for by this instrumentation. For example, retransmissions from packet loss, receiving IP control msgs (like ICMP etc.).

Instrumentation Overhead

In comparison to other kernel events such as thread create or delete, network events are very high frequency events. As a result, extraordinary care has been taken to minimize the overhead of trace instrumentation. The data being collected is primarily from the Transport Control Block (TCB) structure. The fields in the TCB structure are arranged to make the data relevant to capacity planning in one contiguous block. This allows direct copying from the TCB structure to the Trace Buffers without having to make any intermediary copies. In our measurements, a network event uses about 128 x86 instructions and logs 24 bytes of data.

Analysis of sample Traces

Appendix A provides a sample kernel trace fragment from a TCP Send test, translated into readable text format. Each row in the table shows an event instance. Each event instance is described by the fixed header providing the event name, Thread ID that is causing the event, system clock time when the event happened, the kernel and user mode CPU time for the thread. Additional columns in the table show the event specific data associated with each event.

The tests were started after starting up the Trace logger using a command line utility called tracelog.exe. The trace shows the process start and end of the tracelog.exe. Next we see a process start for the TCP send test program (nttcp.exe). Immediately following that we see the Tcp Send events. We can see the source IP address/port and destination IP address/port.

The size of transfers is 8K bytes. The thread that's actually performing the send is (thread Id 0, a system thread). However, the process Id that was saved when the connection was created is 1C0, recorded with every send event. This process Id 1C0 corresponds to the nttcp.exe program that initiated the sends. Hence, we can see that the network traffic can be charged to processes properly from our traces.

While the TCPSend events triggered on the nttcp connection were in progress, an HTTP request for a webpage happened (shown in italics) and through threadID 39C, this request was handled by the IIS running on port 80 and 3 files were sent out to the HTTP remote browser. The HTTP transaction happened through a keep-alive connection. These events were charged to process 382 (InetInfo.exe).

Possible uses of network traces

Classification by PID:

In summary, since stack event trace generated incorporates PID, it is possible to charge network traffic to a specific process or kernel mode service. We will present other possible modes of classification, such as per-service, per-NIC, per-remote-request or per-client as indicated in paragraphs below.

Classification of network utilization per Service:

From post-processing the collected trace information, it is possible to classify the

bandwidth utilization by application / service. Services and user applications / connections can be characterized using the 4-tuple (SAddr, DAddr, Sport, Dport). The traces collected for the specific port show the utilization for a particular service. From the traces shown, it can be observed that (HTTP) web service active on port 80 can be charged for the receives and sends in italics.

Classification of network utilization per NIC:

Using tools such as IPConfig, it is possible to identify NICs and assigned IP addresses. Parsing the collected trace for a specific IP Source Address gives all the traffic for that particular NIC. It is possible that data rerouting can happen when a transfer is in progress. In such a case, TCP receives an indication and a special stack event trace is generated.

Classification of System resource utilization per remote request / client:

Since Disk I/O events are generated in the context of the process, and remote requests are charged to the same process (through stack event traces), it is possible to identify the running service to charge disk i/o operations to. Based on Destination IP addr, this can be further classified per client of the service.

Conclusion

With the introduction of Event Tracing for Windows NT 5.0, we can charge resource consumption of CPU, Memory (Page faults), Disk I/O and Network to applications or Services. This will make the task of capacity planning client/server applications running on Windows NT servers easier and more accurate.

Event Name	**TID**	**Clock (ms)**	**Kt**	**Ut**	**Parent TID**	**Parent PID**	**Sz**	**Image Name**		
ThreadEnd	364	1124573758	0	0	364	1C0				
ThreadEnd	10C	1124573789	1	3	10C	1C0				
ProcessEnd	10C	1124573789	1	3	1C0	288		nttcp.exe		

Legend: Kt - Kernel Mode Time
Ut - User Mode CPU Time
PID - Process ID
TID - Thread ID

The following are the extended record fields for the respective events:

- Process start - new Process Id, its Parent's Process id
- Process end - current Process Id, its Parent's Process id, the image filename that it was running
- Thread start - new thread Id, its Process Id
- Thread end - current thread Id being terminated, its Process Id.
- I/O read, I/O write - The signature of the disk where the I/O operation was done, the transfer size.
- TCPSend - Source Address, Destination Address, Source port, Destination port, Size, ProcessId

Tuesday, December 8, 1998

Session 1

- Yi-Chun Chu: Performance Measurement of the PeopleSoft Multi-Tier Remote Computing Application. 1-25 BibTeX
- Thomas Beretvas: DASD Tuning in the New DASD Environment. 26-38 BibTeX
- Gregory V. Caliri: Getting Started in Mainframe Capacity Planning. 39-43 BibTeX
- Melur K. Raghuraman, Venkat Ramanathan: Network Performance Monitoring in Windows NT. 44-50 BibTeX
- Joel Goldstein: DB2 Buffer Pool Tuning - Top Down or Bottom Up? 51-62 BibTeX
- Brian L. Wong: Comparing MVS and UNIX Workload Characteristics. 63-69 BibTeX
- Steven E. Smead: Service Level Instrumentation 101 - An In-Depth Look at How to Instrument End User Transactions. 70-84 BibTeX
- Daniel P. Ruehl: Business Centric Resource Management Reporting. 85-93 BibTeX

Session 2

- Charles L. Burmaster, Robert Daniel Johnson, Robert H. Johnson: Performance Metric Validation in Chaos. 94-105 BibTeX
- Bruce McNutt: Disk Capacity, Performance, and Cost: Maintaining the Balance. 106-113 BibTeX
- Tim Follen: Capacity Planning and Performance: Tips and Techniques. 114-120 BibTeX
- Mike Tsykin, Christopher D. Langshaw: End-To-End Response Time and Beyond : Direct Measurement of Service Levels. 121-132 BibTeX
- Bernard Domanski: NT Benchmarking. 133-149 BibTeX
- Joseph L. Hellerstein, Fan Zhang, Perwez Shahabuddin: Characterizing Normal Operation of a Web Server: Application to Workload Forecasting and Problem Determination. 150-160 BibTeX
- Ted McGavin: Fibre Channel: The Third Age of Disk Connectivity. 161-165 BibTeX

Session 4

EXHIBIT C

- Linwood Merritt: Getting to Goal Mode. 166-171 BibTeX
- Jaqueline A. Lynch, Richard Milner: User Experience of RVA2 and Snapshot Copy. 172-176 BibTeX
- Andrew L. McCasker: Beyond Availability Management. 177-184 BibTeX
- John F. Maher: Capacity Planning: Are We Still Counting Angles on a Pinhead. 185-189 BibTeX
- Jodi Perry, William J. Raymond, David J. Young: A CICSDB2 Legacy Application takes the Sysplex Plunge. 190-201 BibTeX
- Tachen Leo Lo: Asset Management In a Distributed Computing Environment. 202-208 BibTeX
- Adrian N. Cockcroft: CPU Time Measurement Errors. 209-218 BibTeX
- Geoffrey L. Bradford: Under the Covers: Internals of a Web-Based Network & Systems Performance Reporting System. 219-225 BibTeX
- Andrew Schmitt, Arthur P. Goldberg, Robert Buff: Comparison of HTTP and HTTPS Sever Performance. 226-231 BibTeX

Session 5

- Donald R. Deese: Evaluating and Improving CICS Performance in MVS (Goal Mode). 232-244 BibTeX
- Mark B. Friedman: Optimizing the Performance of Wintel Applications. 245-259 BibTeX
- Richard A. Carlisle: Classical Comparative Analysis Procedures and Deterministic Chaos. 260-271 BibTeX
- Roger P. Botterbusch: Workload Forecasting Issues for World Wide (and Web) Applications. 272-278 BibTeX
- Dale Bryan Drake: Resource Accounting, Cost Allocation & Charge-back in a DFSMS Environment. 279-285 BibTeX
- Richard McDougall: UNIX Memory Usage, Instrumentation and Analysis. 286-290 BibTeX
- Robert J. Michalsky: Load Testing in an Internet World. 291-299 BibTeX
- Hans W. Arnold: TPF - An Operating System for Performance. 300-304 BibTeX

Wednesday, December 9, 1998

Session 1

- Steve C. Lambourne: Will the REAL Parallel Sysplex Please Stand Up. 305-316 BibTeX
- Pat V. Crain, Craig D. Hanson: Oracle Performance Analysis using Wait Events. 317-324 BibTeX
- John C. Tyrrell: How to Stop DFHSM Thrashing in an SMS World. 325-336 BibTeX
- Connie U. Smith, Lloyd G. Williams: Performance Evaluation of Distributed Software Architectures. 337-345 BibTeX
- William G. Pope: Planning Domino Email Servers using Notes Transactions. 346-356 BibTeX
- Brian L. Wong: The Ubiquitous SCSI: What Is It? 357-362 BibTeX
- John Mullen: The Day We Hung Up Our Sandals or Workload Manager in Goal Mode Operation. 363-373 BibTeX
- Ellen M. Friedman, Jerry L. Rosenberg: Countdown to the Millenium: Issues to Consider in the Final Year. 374-387 BibTeX

Session 2

- Stephen L. Samson: The Folly of Ownership Revisited or Whose CICS Region is That, Anyway? 388-393 BibTeX
- Wayne Munson: Introduction To Fibre Channel Connectivity. 394-403 BibTeX

- William G. Pope: A Planning Model for Lotus Notes Applications. 404-408 BibTeX
- Sam Nokes: Estimating Network Traffic for Workload Modeling. 409-421 BibTeX
- Thomas E. Bell, Russell C. Davis: Scrambling To Upgrade Infrastructure Software For Year 2000. 422-430 BibTeX
- Doug V. Johnson: Database Layout Guidelines for Large Queries. 431-436 BibTeX
- Sudhir R. Nath: Capacity Planning and Performance Tuning of the UNIX Systems. 437-447 BibTeX
- Daniel A. Menascé, Nagesh Kakarlamudi: Performance and Availability of Rplicated Database Servers. 448-455 BibTeX

Session 4

- Alan Harbitter, Daniel A. Menascé: Performance Issues in Large Distributed System Security. 456-467 BibTeX
- George W. Dodson: IT Availability - It's Critical to Your Business. 468-487 BibTeX
- Danilo Gotta Luca Biffi: Performance Evaluation of Web Applications. 468- BibTeX
- Richard S. Ralston: A Unique VTS Experience. 488-495 BibTeX
- Hari Sivaraman, Swami Ramany: Scalability Analysis of SCSI Connected IO Systems. 496-506 BibTeX
- Luca Pagliarini, Silvio Pastore Stocchi: From Design to Delivery: A Practical Experience on Performance Prediction. 507-517 BibTeX

Session 5

- Anthony G. Mungal: I/O Concurrency, I/O Bandwidth, Access Density and the Like. 518-527 BibTeX
- Mark W. Johnson: Measuring Service Levels in E-business Applications and Applets. 528-538 BibTeX
- Marco A. Mendes, Virgilio Almeida: Analyzing the Impact of Dynamic Pages on the Performance of Web Servers. 539-547 BibTeX
- Frank M. Bereznay: Who Needs Virtual Tape When You Have Fat DASD? Maybe You Do! 548-555 BibTeX
- Edward A. Woods: Expanding The Reach Of DB2: TCP/IP and DRDA. 556-565 BibTeX

Thursday, December 10, 1998

Session 1

- Irwin F. Kraus: The RMF Type 70 Record: A Plethora of Possibilities. 566-576 BibTeX
- Joseph K. Merton: Organizational Behavior to Systems Implementation Failures. 577-581 BibTeX
- Wayne A. Wyrobek: Tales from the Crypto: Performance Alerts for Mainframe Users of Integrated Cryptographic Facilities. 582-592 BibTeX
- Don O. Koch, Gail Ridgley, Carl Meredith: Using Unix Accounting Utilities for Chargeback Accounting. 593-601 BibTeX
- Harry J. Foxwell, Daniel A. Menascé: Prefetching Results of Web Searches. 602-609 BibTeX
- Jee Fung Pang, Melur K. Raghuraman: Understanding the Windows NT I/O Subsystem. 610-616 BibTeX

Session 2

- H. Pat Artis: DIBs, Data Buffers, and Distance: Understanding the Performance Characteristics of ESCON Links. 617-625 BibTeX
- Jack B. Woolley: Creating a Response Time Agreement for C/S Applications is a Whole New Ballgame! 626-635 BibTeX
- Jodi E. Perry: ARM Yourself for Continuous Availability. 636-642 BibTeX
- Jim Skeen: Data Warehouse Performance: A Methodology for Analysis. 643-654 BibTeX
- Carol E. Kerr: Monitoring Your MS Exchange Server. 655-663 BibTeX
- William Z. Zahavi: The World According to a Storage System. 664-674 BibTeX
- Ronald V. Jones: Performance Monitor - The View From the Driver's Seat. 675-681 BibTeX

Session 4

- Chuck Hopf: "40, 153, 273, 652". 682-697 BibTeX
- Eddie Rabinovitch: Integrating Data in the Enterprise. 698-707 BibTeX
- Mark P. Grinnell: SRDF Remote Copy Performance Test Results. 708-717 BibTeX
- Henry Steinhauer: Network Traffic Analysis at the 20, 000 Foot Level - Or Where Did All This Traffic Come From. 718-721 BibTeX
- Junro Nose, Jun Ohyama: Performance Measurement Methodology: Passive vs. Active. 722-727 BibTeX
- Ilya Pevzner, Arthur P. Goldberg: Characteristics of WWW Proxy Traces. 728-737 BibTeX
- Andy Martin: PC Desktop Performance and Hardware Performance Counters. 738-748 BibTeX
- Kenneth D. Williams: MVS Application Performance Management. 749-760 BibTeX

Session 5

- Adrian N. Cockcroft: Managing the UNIX Mainframe. 761-771 BibTeX
- Joseph K. Merton: Measuring the Effects of Wide Area Networks and Data Transmission. 772-779 BibTeX
- Ronald Dodge, Daniel A. Menascé: Prefetching Inlines to Improve Web Server Latency. 780-788 BibTeX
- Adam Grummitt: Performance Management of Larger Distributed Systems Based on Windows NTT and Ethernet Networks. 789-797 BibTeX
- Alan M. Sherkow: Does Your Installation Have Half-Second I/O Response Time? 798-809 BibTeX
- Yiping Ding, Kenneth Newman: Analyzing Data with Uncertainty. 810-820 BibTeX
- Ferass ElRayes, Jerome A. Rolia, Richard J. Friedrich: The Performance Impact of Workload Characterization Using ARM. 821-830 BibTeX

Friday, December 11, 1998

Session 1

- Donald R. Deese: Analyzing RMF Service Class Data and Workload Activity Reports. 831-841 BibTeX
- Jeffry A. Schwartz: Forecasting Processor Consumption in a Multiple Machine Environment. 842-853 BibTeX
- Mark M. Maccabee: End-To-End Response Time of Lotus Notes Client and Limited Decomposition. 854-862 BibTeX
- Robert Geist, James Westall, Dante M. Treglia: Real-time, 3-D Graphics for the Linux PC. 863-873 BibTeX
- Pierre M. Fiorini, Yiping Ding, Lester Lipsky: On Modeling and Characterizing 'Self-Similar'

Data Traffic. 874-885 BibTeX
- Connie U. Smith, Lloyd G. Williams: Performance Engineering Models of CORBA-based Distributed-Object Systems. 886-898 BibTeX
- Claude Aron, Suresh V. Gadad: Managing 100+ Servers. 899-909 BibTeX
- Brian L. Farrell, Richard Menninger, Stephen G. Strickland: Performance Testing & Analysis of Distributed Client/Server Database Systems. 910-921 BibTeX

Session 2

- Tim R. Norton: Don't Predict Applications When You Should Model the Business. 922-933 BibTeX
- Kelly L. Carr: The Realities of Performance. 934-956 BibTeX
- Paul A. Awoseyi: Performance Optimization in PC Server Environment. BibTeX
- Jozo J. Dujmovic: Optimizing Computer System Configurations. 957-967 BibTeX
- Paul W. Edmiston, Jack Peng, Tachen Leo Lo: Reliability & Availability of Client/Server Networks: An Old Problem in A New Environment. 968-975 BibTeX
- Timothy J. Gibson, Ethan L. Miller, Darrell D. E. Long: Long-term File System Activity and Inter-reference Periods. 976-987 BibTeX
- Alex Patterson: Experiences Migrating a Large Assembler Mainframe Simulator to C++ on a PC. 988-993 BibTeX
- Chuck Hopf: I Did It My Way. 994-998 BibTeX
